# 7. Scheduling: Introduction

**Operating System: Three Easy Pieces** 

# Scheduling: Introduction

- Workload assumptions:
  - 1. Each job runs for the same amount of time.
  - 2. All jobs **arrive** at the same time.
  - 3. All jobs only use the **CPU** (i.e., they perform no I/O).
  - 4. The **run-time** of each job is known.

### **Scheduling Metrics**

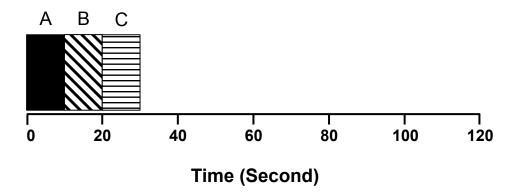

- Performance metric: Turnaround time
  - The time at which the job completes minus the time at which the job arrive
    d in the system.

$$T\downarrow turnaround = T\downarrow completion - T\downarrow arrival$$

- Another metric is fairness.
  - Performance and fairness are often at odds in scheduling.

### First In, First Out (FIFO)

- First Come, First Served (FCFS)
  - Very simple and easy to implement
- Example:
  - A arrived just before B which arrived just before C.
  - Each job runs for 10 seconds.

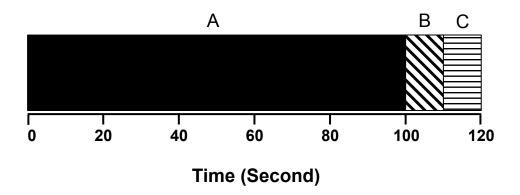

Average turnaround time=10+20+30/3=20 sec

# Why FIFO is not that great? – Convoy effect

Let's relax assumption 1: Each job no longer runs for the same amount of time.

#### Example:

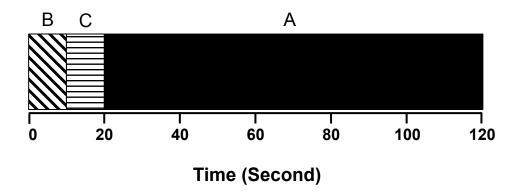

- A arrived just before B which arrived just before C.
- A runs for 100 seconds, B and C run for 10 each.

Average turnaround time=100+110+120/3=110 sec

#### Shortest Job First (SJF)

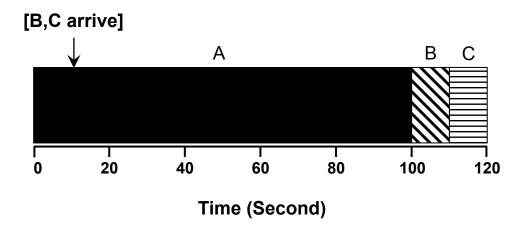

- Run the shortest job first, then the next shortest, and so on
  - Non-preemptive scheduler
- Example:
  - A arrived just before B which arrived just before C.
  - A runs for 100 seconds, B and C run for 10 each.

Average turnaround time=10+20+120/3 =50 sec

#### SJF with Late Arrivals from B and C

- Let's relax assumption 2: Jobs can arrive at any time.
- Example:
  - A arrives at t=0 and needs to run for 100 seconds.
  - B and C arrive at t=10 and each need to run for 10 seconds

Average turnaround time=100+(110-10)+(120-10)/3=103.33 sec

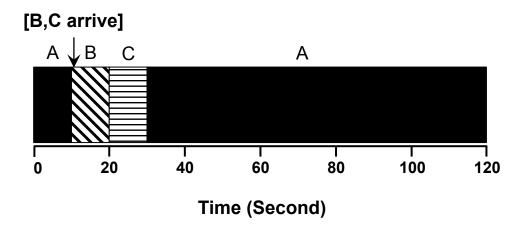

### Shortest Time-to-Completion First (STCF)

- Add preemption to SJF
  - Also knows as Preemptive Shortest Job First (PSJF)
- A new job enters the system:
  - Determine of the remaining jobs and new job
  - Schedule the job which has the lest time left

### Shortest Time-to-Completion First (STCF)

#### Example:

- A arrives at t=0 and needs to run for 100 seconds.
- B and C arrive at t=10 and each need to run for 10 seconds

Average turnaround time=(120-0)+(20-10)+(30-10)/3=50 sec

#### New scheduling metric: Response time

The time from when the job arrives to the first time it is scheduled.

$$T \downarrow response = T \downarrow firstrun - T \downarrow arrival$$

STCF and related disciplines are not particularly good for response time.

How can we build a scheduler that is sensitive to response time?

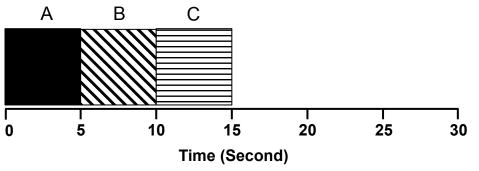

### Round Robin (RR) Scheduling

- Time slicing Scheduling
  - Run a job for a time slice and then switch to the next job in the **run queue** unt il the jobs are finished.
    - o Time slice is sometimes called a scheduling quantum.
  - It repeatedly does so until the jobs are finished.
  - The length of a time slice must be a multiple of the timer-interrupt period.

RR is fair, but performs poorly on metrics such as turnaround time

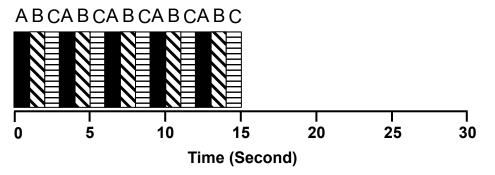

#### RR Scheduling Example

- A, B and C arrive at the same time.
- They each wish to run for 5 seconds.

 $T \downarrow average\ response = 0 + 5 + 10/3 = 5$ 

SJF (Bad for Response Time)

 $T \downarrow average\ response = 0 + 1 + 2/3 = 1$ 

RR with a time-slice of 1sec (Good for Response Time)

#### The length of the time slice is critical.

- The shorter time slice
  - Better response time
  - The cost of context switching will dominate overall performance.

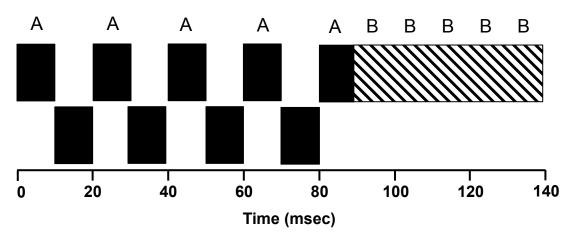

- The longer time slice
  - Amortize the cost of switching
  - Worse response time

Deciding on the length of the time slice presents a trade-off to a system designer

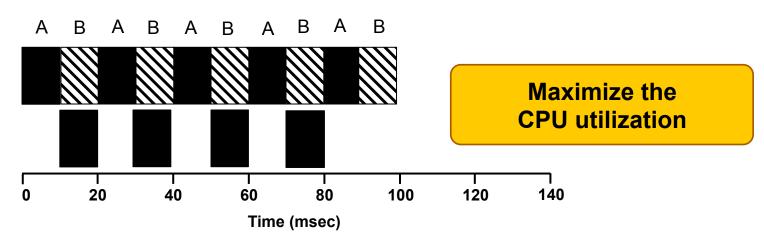

#### Incorporating I/O

- Let's relax assumption 3: All programs perform I/O
- Example:
  - A and B need 50ms of CPU time each.
  - A runs for 10ms and then issues an I/O request
    - I/Os each take 10ms
  - B simply uses the CPU for 50ms and performs no I/O
  - The scheduler runs A first, then B after

# Incorporating I/O (Cont.)

**Poor Use of Resources** 

**Overlap Allows Better Use of Resources** 

### Incorporating I/O (Cont.)

- When a job initiates an I/O request.
  - The job is blocked waiting for I/O completion.
  - The scheduler should schedule another job on the CPU.

- When the I/O completes
  - An interrupt is raised.
  - The OS moves the process from blocked back to the ready state.
